## Degree of a variety

Let $X$ be an affine algebraic variety of pure dimension $d$ over algebraically-closed field $K$ embedded in $K^{N}$.

## Definition

The degree of $X, \operatorname{deg} X$ is the number of points in $X \cap \mathcal{L}$ where $\mathcal{L}$ is a generic codimension- $d$ affine linear space.

$$
\operatorname{deg} X=\#(X \cap \mathcal{L})
$$

For radical ideal $I=\mathbf{I}(X)$, say $\operatorname{deg} I:=\operatorname{deg} X$.

- If $\operatorname{dim} X=0$ then $\operatorname{deg} X=\#(X)$.
- If $X$ is a hypersurface with $\mathbf{I}(X)=\langle f\rangle$, $\operatorname{deg} X=\operatorname{deg} f$.
- Bézout Bound: If $X$ is a complete intersection of hypersurfaces $X_{1}, \ldots, X_{r}$ then $\operatorname{deg} X \leq \operatorname{deg} X_{1} \cdots \operatorname{deg} X_{r}$.

## Computing degree symbolically

## Definition

For ideal $I \subseteq R=K\left[x_{1}, \ldots, x_{N}\right]$, let $R_{n} \subseteq R$ denote the polynomials of degree at most $n$. The Hilbert function of $R / I$ is $\mathrm{HF}_{R / I}: \mathbb{Z}_{\geq 0} \rightarrow \mathbb{Z}_{\geq 0}$ defined by

$$
\operatorname{HF}_{R / I}(n)=\operatorname{dim}_{K}(R / I) \cap R_{n} .
$$

The Hilbert function $\mathrm{HF}_{R / /}(n)$ is polynomial for $n \gg 0$. This polynomial is the Hilbert polynomial of $R / I$, denoted $\mathrm{HP}_{R / I}(n)$.

## Theorem

Suppose the Hilbert polynomial of $R / \mathbf{I}(X)$ is

$$
\operatorname{HP}_{R / l(X)}(n)=a_{d} n^{d}+\cdots+a_{0}
$$

Then

$$
\begin{gathered}
\operatorname{dim} X=d \\
\operatorname{deg} X=d!a_{d}
\end{gathered}
$$

(From this fact we extend the definition of deg / to non-radical ideals and ideals over non-algebraically-closed fields.)
The Hilbert polynomial can be computed from a Gröbner basis.

## Varieties $\mathrm{O}(n)$ and $\mathrm{SO}(n)$

- $\mathrm{O}(n)$ is the subset of $\mathrm{GL}\left(\mathbb{R}^{n}\right)$ preserving the standard inner product.
- $\mathrm{SO}(n)$ is the subset of $\mathrm{O}(n)$ also preserving orientation.

Both $\mathrm{O}(n)$ and $\mathrm{SO}(n)$ are algebraic groups: both groups and algebraic varieties.

$$
\begin{gathered}
\mathrm{O}(n)=\left\{A \in \operatorname{Mat}_{n \times n} \mid A^{T} A=\mathrm{Id}\right\} \subseteq \mathbb{R}^{n^{2}}, \\
a_{i, 1} a_{j, 1}+\cdots+a_{i, n} a_{j, n}=\left\{\begin{array}{ll}
1 & \text { if } i=j \\
0 & \text { if } i \neq j
\end{array} \quad \text { for all } i \leq j .\right.
\end{gathered}
$$

The equations for $\mathrm{SO}(n)$ are the same but adding the degree- $n$ equation

$$
\operatorname{det}(A)=1 .
$$

## Varieties $\mathrm{O}(n)$ and $\mathrm{SO}(n)$

- $\mathrm{O}(n)$ is the subset of $\mathrm{GL}\left(\mathbb{R}^{n}\right)$ preserving the standard inner product.
- $\mathrm{SO}(n)$ is the subset of $\mathrm{O}(n)$ also preserving orientation.

Both $\mathrm{O}(n)$ and $\mathrm{SO}(n)$ are algebraic groups: both groups and algebraic varieties.

$$
\begin{gathered}
\mathrm{O}(n)=\left\{A \in \operatorname{Mat}_{n \times n} \mid A^{T} A=\mathrm{Id}\right\} \subseteq \mathbb{R}^{n^{2}}, \\
a_{i, 1} a_{j, 1}+\cdots+a_{i, n} a_{j, n}=\left\{\begin{array}{ll}
1 & \text { if } i=j \\
0 & \text { if } i \neq j
\end{array} \quad \text { for all } i \leq j .\right.
\end{gathered}
$$

The equations for $\mathrm{SO}(n)$ are the same but adding the degree- $n$ equation

$$
\operatorname{det}(A)=1 .
$$

It's convenient to work in an algebraically-closed field $\mathbb{C}$. From here, take $\mathrm{O}(n)$ and $\mathrm{SO}(n)$ to be the Zariski closures of the above real varieties in $\mathbb{C}^{n^{2}}$, which does not change the degree.

## Some basic facts about $\mathrm{O}(n)$ and $\mathrm{SO}(n)$

## Fact

$$
\operatorname{dim} O(n)=\operatorname{dim} S O(n)=\frac{n(n-1)}{2}
$$

## Fact

$O(n)$ is a complete intersection of $\frac{n(n+1)}{2}$ quadratics.

## Fact

- $\mathrm{SO}(n)$ is a smooth, irreducible variety.
- $\mathrm{O}(n)$ has two disjoint irreducible components, each isomorphic to $\mathrm{SO}(n)$.

## Some basic facts about $\mathrm{O}(n)$ and $\mathrm{SO}(n)$

## Fact

$$
\operatorname{dim} O(n)=\operatorname{dim} S O(n)=\frac{n(n-1)}{2}
$$

## Fact

$O(n)$ is a complete intersection of $\frac{n(n+1)}{2}$ quadratics.

## Fact

- $\mathrm{SO}(n)$ is a smooth, irreducible variety.
- $\mathrm{O}(n)$ has two disjoint irreducible components, each isomorphic to $\mathrm{SO}(n)$.

## Question

What is the degree of $\mathrm{SO}(n)$ ? $\quad(\operatorname{deg} \mathrm{O}(n)=2 \operatorname{deg} \mathrm{SO}(n)$.

## Symbolic computation of deg SO( $n$ )

Symbolic algorithm:

| $\mathbf{n}$ | Symbolic | H.C. | Monodromy | Formula |
| :---: | :---: | :---: | :---: | :---: |
| 2 | 2 |  |  |  |
| 3 | 8 |  |  |  |
| 4 | 40 |  |  |  |
| 5 | 384 |  |  |  |
| 6 | - |  |  |  |
| 7 | - |  |  |  |
| 8 | - |  |  |  |
| 9 | - |  |  |  |

Limitations:

- Gröbner basis time grows badly in number of variables, which is $n^{2}$.
- We could only reach $n=5$.
- For $n$ even or odd we get only 2 data points each.

## Computing degree numerically

Suppose $X$ is a complete intersection, $\mathbf{I}(X)=\left\langle f_{1}, \ldots, f_{r}\right\rangle$ where $r=\operatorname{codim} X$. Choose $\ell_{1}, \ldots, \ell_{N-r}$ random affine linear functionals on $\mathbb{C}^{N}$.

$$
\operatorname{deg} X=\# \mathbf{V}\left(f_{1}, \ldots, f_{r}, \ell_{1}, \ldots, \ell_{N-r}\right)
$$

Numerical algebraic geometry can count the solutions. The total degree homotopy system is

$$
H(t):=t F+\gamma(1-t) G
$$

with

- $F=\left(f_{1}, \ldots, f_{r}, \ell_{1}, \ldots, \ell_{N-r}\right)$,
- $G=\left(x_{1}^{d_{1}}-1, \ldots, x_{r}^{d_{r}}-1, x_{r+1}-1, \ldots, x_{N}-1\right)$ where $d_{i}=\operatorname{deg} f_{i}$ (e.g.),
- $\gamma \in \mathbb{C} \backslash\{0\}$ chosen randomly.

We know all $d_{1} \cdots d_{r}$ solutions to $H(0)=G$. Track solutions of $H(t)$ as $t$ goes from 0 to 1 . Count how many don't go to $\infty$.

## Numerical computation of deg SO(n)

## Homotopy continuation algorithm:

- Recall $\mathrm{O}(n)$ is a complete intersection of $n(n+1) / 2$ quadratics.
- Begin with a "start system" consisting $n(n+1) / 2$ quadratics and $n(n-1) / 2$ linear equations, with known solutions. E.g:

$$
\left\{\begin{array}{l}
a_{i, j}^{2}-1 \quad \text { for } i \leq j \\
a_{i, j} \quad \text { for } i>j
\end{array}\right.
$$

- Continuously deform start system to system for $\mathrm{O}(n) \cap \mathcal{L}$. Track each solution. Limitations:
- Number of paths is $2^{n(n+1) / 2}$. For $n=6$ this is $2^{21}=2097152$.
- We expect deg $\mathrm{O}(6)$ to be much smaller than $2^{21}$.

## Mixed volume

## Definition

For $f \in \mathbb{C}\left[x_{1}, \ldots, x_{N}\right]$,

$$
f=c_{\alpha_{1}} x^{\alpha_{1}}+\cdots+c_{\alpha_{p}} x^{\alpha_{p}}
$$

with $\alpha_{1}, \ldots, \alpha_{p} \in \mathbb{Z}_{\geq 0}^{N}$ and $c_{\alpha_{i}} \neq 0$.
The Newton polytope of $f$ is $\operatorname{conv}\left(\alpha_{1}, \ldots, \alpha_{p}\right)$.
BKK bound: For $\mathbf{I}(X)=\left\langle f_{1}, \ldots, f_{N}\right\rangle$ a complete intersection and $A_{i}$ the Newton polytope of $f_{i}$

$$
\#\left(X \cap\left(\mathbb{C}^{*}\right)^{N}\right) \leq \operatorname{MV}\left(A_{1}, \ldots, A_{N}\right)
$$

where MV is the mixed volume.

- The mixed volume can be much smaller than the Bézout bound.
- This suggests a more efficient homotopy start system: Polynomials with the same Newton polytopes as $\left(f_{1}, \ldots, f_{N}\right)$.
- $\operatorname{MV}\left(A_{1}, \ldots, A_{N}\right)$ can be hard to compute, but we don't need to!
- For $O(n)$, this strategy didn't help us.

## Homotopy continuation results

| $\mathbf{n}$ | Symbolic | H.C. | Monodromy | Formula |
| :---: | :---: | :---: | :---: | :---: |
| 2 | 2 | 2 |  |  |
| 3 | 8 | 8 |  |  |
| 4 | 40 | 40 |  |  |
| 5 | 384 | 384 |  |  |
| 6 | - | - |  |  |
| 7 | - | - |  |  |
| 8 | - | - |  |  |
| 9 | - | - |  |  |

Homotopy continuation computations were performed with the
NumericalAlgebraicGeometry package for Macaulay2 and BERTINI.

## Numerical monodromy computation of deg $\mathrm{SO}(n)$

## Monodromy algorithm:

- Start with a subset of the solutions to $\mathrm{SO}(n) \cap \mathcal{L}$ (perhaps just one point $x_{0}$ ).
- Moving $\mathcal{L}$ through a loop in the Grassmannian back to $\mathcal{L}$ permutes the points in $\mathrm{SO}(n) \cap \mathcal{L}$.

- Tracking known solutions often leads to new ones.
- Repeat this process to populate all of $\mathrm{SO}(n) \cap \mathcal{L}$.
- A solution can't leave its irreducible component, but recall $\mathrm{SO}(n)$ is irreducible.

## Monodromy results

| $\mathbf{n}$ | Symbolic | H.C. | Monodromy | Formula |
| :---: | :---: | :---: | :---: | :---: |
| 2 | 2 | 2 | 2 |  |
| 3 | 8 | 8 | 8 |  |
| 4 | 40 | 40 | 40 |  |
| 5 | 384 | 384 | 384 |  |
| 6 | - | - | 4768 |  |
| 7 | - | - | 111616 |  |
| 8 | - | - | - |  |
| 9 | - | - | - |  |

Monodromy computations were performed in Macaulay2 using the code of Duff-Hill-Jensen-Lee-Leykin-Sommars.

## Kazarnovskij's formula

## Theorem (Kazarnovskij)

Let $G$ be a connected reductive group of dimension $m$ and rank $r$ over an algebraically closed field. If $\rho: G \rightarrow \mathrm{GL}(\mathrm{V})$ is a representation with finite kernel then,

$$
\operatorname{deg} \overline{\rho(G)}=\frac{m!}{|W(G)|\left(e_{1}!e_{2}!\cdots e_{r}!\right)^{2}|\operatorname{ker}(\rho)|} \int_{C_{V}}\left(\check{\alpha}_{1} \check{\alpha}_{2} \cdots \check{\alpha}_{l}\right)^{2} d v .
$$

where $W(G)$ is the Weyl group, $e_{i}$ are Coxeter exponents, $C_{V}$ is the convex hull of the weights, and $\check{\alpha}_{i}$ are the coroots.

- representation: $\rho: \mathrm{SO}(n) \rightarrow \mathrm{GL}\left(\mathbb{C}^{n}\right)$ is the standard embedding.
- kernel: $\operatorname{ker} \rho$ is trivial.
- rank: $r=n / 2$ or $(n-1) / 2$ depending on $n$ even or odd.
- dimension: $m=\binom{n}{2}$.
- size of Weyl group: $|W(\mathrm{SO}(n))|=r!2^{r-1}$ or $r!2^{r}$.
- Coxeter exponents: $e_{1}, \ldots, e_{r}=1,3, \ldots, 2 r-3, r-1$ or $1,3, \ldots, 2 r-1$.
- weights: $\pm e_{1}, \ldots, \pm e_{r}$.
- coroots: $\left\{\check{\alpha}_{1}, \ldots, \check{\alpha}_{l}\right\}=\left\{x_{i}^{2} \pm x_{j}^{2}\right\}_{1 \leq i<j \leq r}$ or $\left\{x_{i}^{2} \pm x_{j}^{2}\right\}_{1 \leq i<j \leq r} \cup\left\{x_{i}^{2}\right\}_{1 \leq i \leq r}$.

## Degree formulas

## Proposition (Recht-Robeva)

$$
\begin{aligned}
\operatorname{deg} \mathrm{SO}(2 r) & =\frac{\binom{2 r}{2}!}{r!2^{r-1}(r-1)!^{r-1}(2 k-1)!_{k=1}^{2}} \int_{C_{V}}\left(\prod_{1 \leq i<j \leq r}\left(x_{i}^{2}-x_{j}^{2}\right)^{2}\right) d v, \\
\operatorname{deg} \mathrm{SO}(2 r+1) & =\frac{\binom{2 r+1}{2}!}{r!2^{r} \prod_{k=1}^{r}(2 k-1)!^{2}} \int_{C_{V}}\left(\prod_{1 \leq i<j \leq r}\left(x_{i}^{2}-x_{j}^{2}\right)^{2} \prod_{i=1}^{r}\left(2 x_{i}\right)^{2}\right) d v .
\end{aligned}
$$

where $C_{V}$ is the cross polytope $C_{V}=\operatorname{conv}\left( \pm e_{1}, \ldots, \pm e_{r}\right) \subseteq \mathbb{R}^{r}$.

## Degree formulas

## Proposition (Recht-Robeva)

$$
\begin{aligned}
& \operatorname{deg} \mathrm{SO}(2 r)=\frac{\binom{2 r}{2}!}{r!2^{r-1}(r-1)!^{2}} \prod_{k=1}^{r-1}(2 k-1)!^{2} \\
& \int_{C_{v}}\left(\prod_{1 \leq i<i \leq r}\left(x_{i}^{2}-x_{j}^{2}\right)^{2}\right) d v, \\
& \operatorname{deg} \mathrm{SO}(2 r+1)=\frac{\left(\begin{array}{c}
2 r+1
\end{array}\right)!}{r!2^{r} \prod_{k=1}^{r}(2 k-1)!^{2}} \int_{C_{v}}\left(\prod_{1 \leq i<i \leq r}\left(x_{i}^{2}-x_{j}^{2}\right)^{2} \prod_{i=1}^{r}\left(2 x_{i}\right)^{2}\right) d v .
\end{aligned}
$$

where $C_{V}$ is the cross polytope $C_{V}=\operatorname{conv}\left( \pm e_{1}, \ldots, \pm e_{r}\right) \subseteq \mathbb{R}^{r}$.
To evaluate these integrals:

- $C_{V}$ has a standard simplices $\Delta_{r}$ in each orthant, and the integrand is even in each $x_{i}$.
- Rewrite the integrand as a sum of monomials with identity:

$$
\prod_{1 \leq i<j \leq r}\left(y_{j}-y_{i}\right)=\sum_{\sigma \in S_{r}} \operatorname{sgn}(\sigma) \prod_{i=1}^{r} y_{i}^{\sigma(i)-1}
$$

- Monomials integrate as $\int_{\Delta_{r}} x_{1}^{a_{1}} \cdots x_{r}^{a_{r}} d x=\frac{1}{\left(r+\sum a_{i}\right)!} \prod_{i=1}^{r} a_{i}!$.

Theorem

$$
\operatorname{deg} \mathrm{SO}(n)=2^{n-1} \operatorname{det}\left[\binom{2 n-2 i-2 j}{n-2 i}\right]_{1 \leq i, j \leq\left\lfloor\frac{n}{2}\right\rfloor} .
$$

## Example

$$
\begin{aligned}
& \operatorname{deg} S O(4)=2^{4-1} \operatorname{det}\left[\begin{array}{ll}
4 \\
2 \\
2
\end{array}\right)\left(\begin{array}{l}
2 \\
2 \\
0
\end{array}\right) \\
& \left.\operatorname{deg} S O(5)=2^{5-1} \operatorname{det}\left[\begin{array}{ll}
6 \\
3 \\
3 \\
1
\end{array}\right)\left(\begin{array}{l}
4 \\
3 \\
1 \\
1
\end{array}\right)\right]=384 \text {. }
\end{aligned}
$$

Theorem

$$
\operatorname{deg} \operatorname{SO}(n)=2^{n-1} \operatorname{det}\left[\binom{2 n-2 i-2 j}{n-2 i}\right]_{1 \leq i, j \leq\left\lfloor\frac{n}{2}\right\rfloor} .
$$

## Example

$$
\begin{aligned}
& \operatorname{deg} S O(4)=2^{4-1} \operatorname{det}\left[\begin{array}{ll}
4 \\
2 \\
2
\end{array}\right)\left(\begin{array}{l}
2 \\
2 \\
0
\end{array}\right) \\
& \left.\operatorname{deg} S O(5)=2^{5-1} \operatorname{det}\left[\begin{array}{ll}
6 \\
3 \\
3 \\
1
\end{array}\right)\left(\begin{array}{l}
4 \\
3 \\
2 \\
1
\end{array}\right)\right]=384 \text {. }
\end{aligned}
$$

## Real points in $\mathrm{SO}(n)$

## Question

How many real points can $\mathrm{SO}(n) \cap \mathcal{L}$ have (for $\mathcal{L}$ real)?

- $\mathrm{SO}(2)$ is a circle, so $\mathrm{SO}(n) \cap \mathcal{L}$ can have 0 or 2 real points.
- The number of real points is always even.
- The number is "usually" zero since $\mathrm{SO}(n) \cap \mathbb{R}^{n^{2}}$ is compact.

Taylor Brysiewicz computed the number of real points of $\mathrm{SO}(n) \cap \mathcal{L}$ many randomly chosen $\mathcal{L}$ by:

- using the monodromy algorithm to compute all solutions,
- using alphaCert ify to determine which solutions are real.

## Experimental results

Frequency of each number of points in $\mathrm{SO}(n) \cap \mathcal{L}$ :

| \#(Real Solutions) | $n=3$ | $n=4$ | $n=5$ |
| :---: | ---: | ---: | ---: |
| 0 | 340141 | 95566 | 1739 |
| 2 | 500250 | 56795 | 776 |
| 4 | 655908 | 69501 | 659 |
